## Abstract

**Background:** Oxidative stress (OS) contributes to the development of some disorders, including malignancies, metabolic diseases, Alzheimer's disease, and Parkinson's disease.

**Objectives:** The effects of coenzyme  $Q_{10}$  (Co $Q_{10}$ ) supplementation on OS parameters have been assessed through an updated systematic review and meta-analysis.

**Methods:** Scopus, PubMed, Cochrane Library, EMBASE, and Web of Sciences were used for article searching. Standardized mean difference (SMD) and its standard error were calculated using a random-effects DerSimonian and Laird model. All analyses were done using the STATA software version 16.0 (StataCorp, College Station, TX).

**Results:** Based on twenty-five studies which remained to be incorporated in the meta-analysis, a statistically significant decrease in malondialdehyde (MDA) (SMD -2.74; 95% CI -3.89, -1.58;  $I^2 = 96.9\%$ ) as well as nitric oxide (NO) (SMD -5.16; 95% CI -7.98, 2.34;  $I^2 = 92.5\%$ ) was associated with CoQ<sub>10</sub> supplementation, and a significant increase in total antioxidant capacity (TAC) (SMD 3.40; 95% CI 1.98, 4.83;  $I^2 = 97.4\%$ ) and superoxide dismutase (SOD) activity (SMD 1.22; 95% CI 0.32, 2.12;  $I^2 = 94.32\%$ ).

**Conclusions:** The results showed no significant effect of  $CoQ_{10}$  supplementation on glutathione peroxidase (GPx), catalase (CAT) activities, and glutathione (GSH) levels. Coenzyme  $Q_{10}$  supplementation significantly reduced MDA and NO concentrations and increased TAC and SOD activity.

Keywords: Coenzyme Q10, Oxidative Stress, Superoxide Dismutase, Malondialdehyde, Total Antioxidant Capacity

#### 1. Background

Extensive research shows that dietary antioxidants could protect body cells against free radicals. Ubiquinone, also known as coenzyme  $Q_{10}$  (Co $Q_{10}$ , 2,3-dimethoxy-5-methyl-6-decaprenyl benzoquinone), is an important endogenous cellular antioxidant (1). The human body and other living organisms, normal cellular metabolism, and environmental factors, such as air pollutants, can produce reactive oxygen species (ROS). This process which disturbs the balance between oxidants and antioxidants, is called oxidative stress (OS). The OS can cause damage to cell structures such as carbohydrates, nucleic acids, lipids, and proteins functions and contributes to the development of many diseases, such as cancer, diabetes, atherosclerosis, hypertension, chronic obstructive pulmonary disease, and so on (2, 3). In addition to the natural process of produc-

ing oxidative stress in the body, cells exercising with different intensities can induce oxidative stress, leading to fatigue, muscle damage, and impaired performance (4). Despite the many known health benefits of exercise, evidence shows that resistance and endurance exercise causes oxidative stress. During the mentioned activities, the body's oxygen consumption increases, which produces more ROS in the body. Since the amount of ROS produced exceeds the body's ability to detoxify them, some of them remain in the body and cause oxidative injury (5, 6). With the increase in aerobic exercise intensity, these damages will be increased (6). Numerous studies have shown the effect of coenzyme Q<sub>10</sub> on oxidative stress and its ability to scavenge against various free radicals (7-11). This supplement can reduce cellular oxidant activities in normal conditions, exerciseinduced oxidative stress in damaged muscle, and improve

various aspects of exercise performance at different intensities (4). Coenzyme Q<sub>10</sub> is poorly absorbed in electrons; as a result, it loses one or two electrons and is easily oxidized. The coenzyme Q<sub>10</sub> is a powerful antioxidant characterized by the rapid uptake and loss of electrons (12). Coenzyme Q<sub>10</sub> inhibits the production of free radicals (13). Coenzyme  $Q_{10}$  regenerates vitamin E from  $\alpha$ -tocopherol radicals (14). OS overproduction of reactive oxygen species is an important factor in developing diseases (ROS) (8). OS reveals an imbalance between ROS and the ability to repair the damage. Instabilities in the normal redox state of cells can cause toxic effects by producing free radicals that damage all components of the cell, including DNA. OS causes base damage and DNA strand breaks (15). The dietary composition can alter antioxidant mechanisms (16). Many randomized clinical trials (RCTs) and a few systematic reviews have investigated the impact of CoQ<sub>10</sub> on oxidative stress (8, 17-19), but the results of systematic reviews about the effect of CoQ<sub>10</sub> supplementation on oxidative stress seem to be inconclusive.

## 2. Objectives

The effects of coenzyme  $Q_{10}$  (Co $Q_{10}$ ) supplementation on OS parameters were assessed through an updated systematic review and meta-analysis.

## 3. Methods

#### 3.1. Search Strategy

MEDLINE, Web of Science, Scopus, Cochrane Library, and ClinicalTrials.gov were searched using the following keywords:

Glutathione Reductase OR Glutathione Peroxidase OR Superoxide Dismutase OR Nitric Oxide OR Oxidative Stress OR Malondialdehyde OR Total Antioxidant Capacity OR Total Antioxidant Status OR antioxidant OR Oxidant OR reactive oxygen species OR ROS OR Catalase OR reactive nitrogen species OR protein carbonyl) AND (Coenzyme Q<sub>10</sub> OR "Q<sub>10</sub>" OR CoQ<sub>10</sub> OR Ubiquinone OR Bio-Quinone Q<sub>10</sub> OR Ubisemiquinone radical OR Ubisemiquinone OR Ubiquinol-10 OR Ubiquinol.

## 3.2. Inclusion and Exclusion Criteria

The independent reviewers selected two randomized placebo-controlled studies on adults (18 years or older) that evaluated the effects of CoQ<sub>10</sub> on malondialdehyde (MDA), glutathione (GSH), nitric oxide (NO) levels, glutathione peroxidase (GPx), catalase (CAT), superoxide dismutase (SOD) activities, and total antioxidant capacity (TAC), and were published between 2000 and 1st May 2022.

#### 3.3. Data Extraction

Two authors performed data extraction and quality assessment of included studies independently. First author's name; type of participant disease; sample size; year of publication; the dose and duration of supplementation; age; body mass index (BMI); gender of participants; and outcome variables (CAT, TAC, MDA, GPx, GSH, NO, and SOD).

## 3.4. Assessment of Quality

The Cochrane risk of a bias assessment tool which assesses the adequacy of randomization sequence generation, allocation concealment, blinding, incomplete outcome data, attrition bias, and other potential sources of bias, was used for quality assessment.

#### 3.5. Statistical Analysis and Data Synthesis

Firstly, the mean changes from the baseline to the end of the study period were extracted for each included study. In the second step, the correlation coefficient was calculated separately for the experimental and control groups as follows:

$$Corr_{E} = \frac{SD_{E.\ baseline}^{2} + SD_{E.\ final}^{2} - SD_{E.\ change}^{2}}{2 \times SD_{E.\ baseline} \times SD_{E.\ final}}$$

The SD changes from the baseline calculated using the correlation coefficient for each group separately as follow:

$$SD_{E.\,change} = \sqrt{SD_{E.\,baseline}^{2} + SD_{E.\,final}^{2} - (2 \times Corr \times SD_{E.\,baseline} \times SD_{E.\,final})}$$

Cochran's Q test and  $I^2$  statistics were used to assess the heterogeneity between the studies. A high amount of  $I^2$  (more than 75%) refers to the presence of heterogeneity. The random-effects DerSimonian and Laird model was used to calculate the pooled mean difference according to significant heterogeneity between studies. The publication bias was assessed by Begg's and Egger's tests. Moreover, the heterogeneity between the studies was determined via meta-regression analysis. The significance level for Begg's and Egger's tests was 0.1, and for other tests, 0.05 was considered a significant level. All analyses were done using STATA software version 16.0 (StataCorp, College Station, TX).

#### 4. Results

#### 4.1. Study Selection Process

Searching electronic databases led to 4158 records. Firstly, the found studies were screened using the title, abstract or full text. In this step, 274 articles were assessed for eligibility using the full text. Of these, 25 RCTs had inclusion criteria used for the final analysis. The screening steps of the studies are presented in Figure 1. The total of understudied cases in the studies was equal to 1169 people. The range of sample sizes varied from 20 to 100. Most of the studies were performed in Iran (16 papers). The doses of  $CoQ_{10}$  prescribed in the included studies were from 30 to 400 mg per day, and the duration of supplement administration in different studies was between 1 and 24 weeks. More detail is shown in Table 1.

# 4.2. Effect of Coenzyme $Q_{10}$ Supplementation on Oxidative Stress Parameters

The MDA level was evaluated in 17 records. Coenzyme Q<sub>10</sub> significantly reduced MDA levels in the intervention group compared to the control group (standardized mean difference (SMD) - 2.74; 95% CI -3.89, -1.58; I<sup>2</sup> = 96.9%) (Figure 2). Results showed that CoQ<sub>10</sub> significantly reduced MDA levels in patients younger than 50 years (SMD -8.24; 95% CI -10.91, -5.57;  $I^2 = 97.5\%$ ). The intervention dose not significantly decrease MDA levels among patients older than 50 years (SMD -0.23; 95% CI -1.42, 0.95;  $I^2 = 96\%$ ). Results showed that in patients with BMI < 25, CoQ<sub>10</sub> supplementation significantly decreased MDA levels (SMD -7.53; 95% CI -10.87, -4.19;  $I^2 = 97$ . 5%). The intervention also significantly decreases MDA levels among patients with BMI  $\geq$  25 (SMD -1.55; 95% CI -2.37, -0.32;  $I^2 = 96.67\%$ ). According to different doses, CoQ<sub>10</sub> at a dose of less than 200 significantly reduced MDA levels (SMD -5.02; 95% CI -6.64, -3.40; I<sup>2</sup> = 97.2%). Also, CoQ<sub>10</sub> at a dose of more than 200 did not had significantly effect on MDA levels (SMD 0.37; 95% CI -1.47, 2.20; I<sup>2</sup> = 96.5%).

The effects of  $CoQ_{10}$  supplementation on CAT activity were evaluated in seven records. Comparison to control group,  $CoQ_{10}$  does not have significant effects on CAT activity (SMD 1.83; 95% CI -1.10, 4.76;  $I^2 = 98.3\%$ ). Also, different doses of  $CoQ_{10}$  supplementation showed the same results, but the results were significant in patients with age > 50 and BMI > 25 (Figure 2).

The effects of  $CoQ_{10}$  supplementation on GPx activity were evaluated in six records. According to pooled analysis,  $CoQ_{10}$  does not have significant effects on GPx activity (SMD 1.01; 95% CI -0.97, 2.99;  $I^2 = 97.5\%$ ) (Figure 2). Two studies evaluated the effects of  $CoQ_{10}$  supplementation on plasma NO. According to results,  $CoQ_{10}$  supplementation significantly reduced plasma NO concentrations among intervention groups compared to the control group (SMD -5.16; 95% CI -7.98, -2.34;  $I^2 = 92.5\%$ ) (Figure 2).

The effect of  $CoQ_{10}$  supplementation on SOD activity was assessed in nine records. According to a pooled analysis,  $CoQ_{10}$  supplementation significantly increased SOD activity among the intervention groups (SMD 1.22; 95% CI 0.32, 2.12; I<sup>2</sup> = 94.32%) (Figure 2). According to a pooled analysis of 20 records,  $CoQ_{10}$  supplementation significantly increased TAC levels among the intervention groups (SMD 3.40; 95% CI 1.98, 4.83;  $I^2 = 97.4\%$ ) (Figure 2). About the effects of CoQ<sub>10</sub> supplementation on GSH levels, the analysis was not showed a significant difference between intervention and placebo group (SMD 5.16; 95% CI -3.25, 13.57;  $I^2 = 99.2\%$ ) (Figure 2).

Table 2 shows each OS indexes overall and stratified pooled SMD estimation. Overall, the risk of bias among understudied papers was low. More than 70% of the included studies met the random sequence generation. However, allocation concealment and blinding were considered in more than 50% of studies (Figure 3).

## 4.3. Meta-regression Analysis

According to a simple meta-regression analysis, the study year and sample size do not significantly affect heterogeneity between studies about the understudied factors (P > 0.05).

#### 4.4. Publication Bias

According to Begg's and Egger's tests, there was significant publication bias about the CAT, GPx, GSH, and NO. Nevertheless, Egger's test showed publication bias for MDA, SOD, and TAC (P = 0.01, 0.02, 0.003, respectively).

#### 5. Discussion

The current study results are consistent with previous studies (8, 22, 38, 39), showing that supplementation with CoQ<sub>10</sub> significantly improves OS parameters. It increases TAC levels and SOD activities and decreases MDA and NO levels. However, this supplementation does not affect GSH or CAT levels. Also, the present study results, in line with other studies, showed that supplementation with CoQ<sub>10</sub> does not change GPx activity (40). There are few metaanalyses about the effects of CoQ<sub>10</sub> supplementation on OS profile. A meta-analysis by Akbari et al. showed a significant decrease in MDA (39). Another meta-analysis showed that the CoQ<sub>10</sub> supplementation increased SOD and CAT while decreasing MDA levels (38). According to our results, CoQ<sub>10</sub> supplementation significantly increases SOD in addition to the abovementioned factors. Antioxidant enzymes are the first defense barrier against ROS, and their reduction in the body will lead to increased OS (41). A study has shown that a daily intake of 150 mg of CoQ<sub>10</sub> supplementation significantly decreases oxidative stress and increases the activity of antioxidant enzymes (42).

 $CoQ_{10}$  protects cells against apoptosis and OS damage (43). Apoptotic proteins like Bax lead to caspase-induced apoptosis by increasing cytochrome c release (38). On the other hand, anti-apoptotic proteins such as Bcl-2, by combining with Bax and reducing the release of cytochrome c, inhibit the apoptotic process (44). Caspase-3 can cause

DNA fragmentation and, eventually, apoptosis (45, 46). However, this process was reversed by  $CoQ_{10}$  (47).

Subgroup analyzes of our results show that  $CoQ_{10}$  supplementation significantly increases TAC in overweight and obese individuals. Evidence suggests that obesity-related factors, including hyperglycemia, dyslipidemia, and increased adipose tissue, are important factors associated with oxidative stress (48).

In addition, our results showed that taking  $CoQ_{10}$  at a dose of > 200 mg daily significantly changed TAC levels. Another study showed that higher doses of  $CoQ_{10}$  may have faster and more stable antioxidant effects (42).

Our study results showed that  $CoQ_{10}$  supplementation also significantly reduced MDA levels. MDA is a polyunsaturated fatty acids peroxidation product (49). Coenzyme  $Q_{10}$ supplementation protects against lipid peroxidation, regulates lipid metabolism, and prevents lipid oxidation (50). Coenzyme  $Q_{10}$  also limits the production of endogenous ROS in mitochondria (8, 51) and is usually related to decreased MDA levels (52). Coenzyme  $Q_{10}$  is the main element of the antioxidant process in all parts of the cells (53) and can reduce ROS and free radicals levels, produced by the reaction with oxygen radicals or lipids through a direct reduction back to the tocopherol, resulting in improvement of oxidative stress (54).  $Q_{10}$  supplementation may reduce plasma lipid peroxidation and regenerate tocopherol radicals (55).

Our systematic review and meta-analysis results, consistent with other studies (34, 56), show that  $CoQ_{10}$  supplementation significantly affected SOD activity. Coen-

zyme  $Q_{10}$  can play an antioxidant role by reducing ROS in mitochondria, thereby changing SOD activity (57). Despite a nonsignificant difference between intervention and placebo groups, the results of our study showed that  $CoQ_{10}$  supplementation changed CAT activity. The few primary studies may be why we could not find a significant effect of  $CoQ_{10}$  supplementation on CAT activity. This study showed that  $CoQ_{10}$  supplementation improves TAC and MDA concentrations and SOD and NO activity compared with placebo. Finally,  $CoQ_{10}$ , as a generally safe and well-tolerated supplement, could be considered for treating and preventing some human disorders. Furthermore,  $CoQ_{10}$  can be used as an important adjuvant in treating different elderly diseases and chronic conditions.

## 5.1. Conclusions

 $CoQ_{10}$  supplementation significantly reduces MDA and NO concentrations and increases TAC and SOD activity. However, the effects of  $CoQ_{10}$  supplement on NO, GSH concentrations, or CAT activity were not statistically significant. It should be regarded that more interventional studies, such as clinical trials with higher sample sizes, are needed to assess the impact of  $CoQ_{10}$  supplementation on oxidative stress parameters.

## Footnotes

Authors' Contribution: A S, M S study concept and design. A S, M S, and M S participated in article searching and screening, performed the statistical analysis, and helped to draft the manuscript. H SH, W T participated in the article screening, manuscript writing, and revision. All authors read and approved the final manuscript.

**Conflict of Interests:** The authors clarify that this study does not have any funding support; also, they have no affiliations with or involvement in any organization or entity with any financial interest (such as honoraria; educational grants; membership, employment, consultancies, stock ownership, participation in speakers' bureaus, or other equity interest; and expert testimony or patent-licensing arrangements), or non-financial interest (such as personal or professional relationships, affiliations, knowledge or beliefs) in the subject matter or materials discussed in this manuscript. Also, the authors declare that this study did not have patents, and the authors do not have any relations with editorial board members or journal reviewers.

**Data Reproducibility:** No new data were created or analyzed in this study. Data sharing does not apply to this article.

Funding/Support: This study had no funding resources.
