(Received:30 Apr 2011; Revised: 24 Dec 2011; Accepted: 14 Jun 2012)

Background: More psychiatric visits, especially non-emergency ones, to emergency departments (EDs) of general hospitals have been observed in recent years. The aim of this study was to determine the characteristics of psychiatric visits to the ED of Rasoul-e-Akram Hospital, Tehran, Iran.

Methods: In this cross-sectional study, during a two-month period, all psychiatric presentations and consultations to the ED of the studied hospital were included. The required data were gathered by psychiatry chief residents and were documented in pre-designed checklists.

Results: About 0.01% of all patients presenting to the ED needed the psychiatric visits. Men consisted 50% of the total patients with mean (\pm SD) age of 36.41 (\pm 14.7) years. About 51% of them had the indication of the emergency psychiatric visit while 47% had the indication of hospitalization in the psychiatric ward. Non-emergency visits were not related to demographic characteristic, previous psychiatric disorders, substance abuse and physical diseases

Conclusions: Non-emergency visits take a high percentage of psychiatric visits in ED and regarding limited sources for psychiatric emergencies and Long visiting time, this percentage can hinder the process of giving services to real emergency psychiatric patients.

Declaration of interest: None.

Key words: •Emergency •Indication •Psychiatric visit

Introduction

The number of psychiatric patients presenting to EDs has increased in different countries in recent years. Similarly, there has been a 38% increase in psychiatric visits to EDs in the US from 1992 to 2001(1). In addition, a study from National American College of Emergency Physicians demonstrated a 61.3% increase in patients presenting to psychiatric emergencies EDs in a course of 6 to 12 months

(2). Besides in other countries, psychiatric visits to EDs have increased due to an increase in the number of psychiatric units of general hospitals (3-5).

Regarding this increase, many studies have been carried out about demographic characteristics, symptoms and disorders, the reasons of referrals and admission indications of mental health patients in EDs in many countries (6-9).

As far as we know, there are few similar studies in our country about the percentage and characteristics of psychiatric visits to the EDs of general hospitals. In this study, the authors intended to investigate some characteristics of psychiatric visits to the ED of Rasoul-e-Akram hospital. This general hospital has affiliation to Tehran University of Medical Sciences, Tehran,

Iran. This center has no selective admission policy and admits patients from all over the country.

Materials and Methods

In this cross-sectional study, all emergency psychiatric visits to the studied hospital in a two-month period were studied. The data was collected by psychiatric chief residents, who had passed courses in diagnosing and treating emergency psychiatric problems, and recorded the required data inside pre-designed checklists made by the researchers. The data consisted of demographic characteristics, the time of request of visit, length of each visit, past history of psychiatric disorders, medical disease, substance abuse, emergency visit indication, need of hospitalization and its reason, need of revisiting and its reason and the process of discharging the patient. The information was gathered by interviewing the patient and their relatives and reviewing their files. The mean duration of information gathering time was 45 minutes. The emergency visit indication was determined based on clinical judgments of psychiatric residents and indications such as the danger of self-harm and harm to others, crisis encounter, symptoms of substance intoxication or withdrawal or treatment side-effects requiring immediate intervention.

The need for hospitalization was also determined based on indications such as self-harm or harm to others, not responding to outpatient treatments, not having enough support or existence of environmental psychological stresses, especial treatment aims and judicial orders.

To analyze data, using the SPSS software for Windows (Version 15), and descriptive indices were used to express data and the student t-test and logistic regression were used to interpret data.

Results

In a course of 2 months, 102 psychiatric visits were done in the ED of Rassoul-e-Akram

hospital which was 0.01% of all 10124 visits to the ED of this hospital. There were 51 men (50%) and 51 women (50%). The average age of patients was 36.41 ± 14.7 years (range, 14-73). Other demographic characteristics of patients such as marital status, occupation and

Table 1. Demographic features of mental health-related ED visits.

Variables	Frequency (%)
Marital status	
Married	52(51)
Single	45(44)

educational level are shown in table 1.

Mean time of calling the resident and starting the visit was 14.6 ± 5.9 minutes (range, 10-40 minutes). Mean length of visiting time was 41.68 ± 22.36 minutes (range, 5-120).

Forty-six patients (45.1%) had previously diagnosed by psychiatric disorders, 31 cases (31.4%) had previous or current substance abuse and 30 cases (29.4%) had medical diseases.

Fifty-two patients (51%) had indication of emergency psychiatric visit and the remainder (50 patients, 49%) either came to the ED for non-emergency reasons or emergency physicians requested psychiatric consultation for non-emergency conditions. The frequency distribution of emergency visit indication based on other variables such as age, gender, educational level, and so on is shown in table 2.

Twenty-eight patients (27.45%) were asked to present for a second visit, 9 patients (32%) for further diagnostic investigations, 8 cases (28.6%) with suspicion of having organic problems, 8 patients (28.6%) for not having good conditions for the interview due to the low consciousness or emergency medical problems, and 3 patients (10.8%) for other reasons.

Table 2. The frequency distribution of emergency visit indication based on other variables

Variables	Indication of emergency psychiatric visit		P value	df
	Yes	No		
Gender (%)				1
Female	25(48%)	26 (52%)	0.295	
Male	27 (52%)	24 (48%)

Previous psychiatric disorders	30(%57.7)	16(%32)	0.56	1
Previous or current substance abuse	18(%34.6)	13(%26)	0.659	1
Comorbid medical diseases	14(26.9%)	16(32%)	0.2	1

Forty-eight patients (47%) had indication to be hospitalized in psychiatric ward of the hospital (Table 3).

Table 3. Indication of hospitalization and the reason of not hospitalizing

Variables	Frequency (%)
Indication of hospitalization	
The risk of self-harm	29 (60.42)
The risk of harm to others	25 (52.08)
Not responding to outpatient treatments	15 (31.25)
Special treatment aims	7(14.58)
Drug side effects (ex. NMS)	7 (14.58)
existence of environmental psychological stresses	3 (6.25)
Not having enough support	1 (2.08)
Hospitalization	
Yes	32 (66.7)
No	16 (33.3)
The reason of not hospitalizing	
Not having enough beds	12 (75)
Not having facilities	3(18.75)
Family didn't consent to hospitalization	1(6.25)

The need to be hospitalized had no significant statistical relationship with age ($p=0.024$, $df=6$), level of education ($p=0.866$, $df=4$), marital status ($p=0.2$, $df=3$), gender ($p=0.832$, $df=1$), and the current substance abuse ($p=0.426$, $df=1$). However, need for hospitalization showed significant relationship

with occupation ($p<0.01$, $df=1$), medical disease ($p<0.01$, $df=1$), and previous psychiatric disorders ($p<0.01$, $df=1$), in a way that more hospitalization indications were observed in unemployed people and patients with medical diseases or past history of psychiatric disorders compared to those who did not meet these criteria (Table 4).

Table 4. The frequency distribution of hospitalization indication based on other variables

variables	Indication of hospitalization			P value	df
	Yes	No

Previous or current substance abuse	17(35.42)	14(25.92)	0.426		1

Discussion

The present study showed that of all emergency visits, 0.01% was due to psychiatric reasons which is much less than reported figures from other countries which is between 2 and 2.5%. The reason for this considerable difference is not related to number of psychiatric visits because in other countries the average visits was between 60-90 people per month in comparison with the 50 people in our study. However the real reason maybe is the great number of visitors to the ED of the Rasoul-e-Akram Hospital as a major hospital in Tehran (1, 4, 8). In this study, only 51% of patients had the indication of emergency psychiatric visit. It is very common to see non-urgent use of EDs in many parts of the world

and all medical fields and it is reported that such visits take 85-95% of visits. Surprisingly, outpatient visits had a 50% increase from 1955 to 1970, whereas emergency visits increased by 312% in the same period in the US (10). Although 52% is more heartwarming than 85-95% for non-urgent medical visits in EDs in other countries, regarding limited sources for psychiatric emergencies, long visiting times (which was in average 42 minutes in this study) and the need to have special facilities for such visits, this percentage can still hinder the process of giving services to real emergency psychiatric patients (11).

In this study, no demographic characteristics were related to non-emergency visits to the ED. Results of most studies about the gender of non-emergency visits to emergency wards are different. Some, like the present study, showed no difference between genders (12, 13) and some have suggested that it is more common in men (14) or in women (15). Unlike the probability of having more visits from the older patients, in this and most studies, the age range of patients was between 20 and 40 years of age which is in accordance with the age range of all visitors to the EDs (12, 13).

In some studies it is reported that having low social support, living alone and being single are related to non-urgent use of EDs (16, 17). However, in this study, marital status was not related to this issue which is probably because of the fact that in our country the immediate family consisting father, mother and siblings is still a very important provider of support, and being single does not necessarily show isolation and lack of social support. It is clear that carrying out studies with more samples with the aim of analyzing social support with special questionnaires can clarify the relation between social support and non-urgent use of EDs. In this study, job status as a mark of economic status was not in any relation with non-emergency psychiatric visits in the ED. Although some studies have shown economic status to be related to non-urgent use of EDs, race influences this relation. As was seen,

economic status in whites has a reverse relation with non-emergency visits in ED, but for black economic conditions are not in any relation to non-emergency visits (12, 18). On the one hand, poverty and being covered by insurance are the benefits of emergency service especially for unemployed people with poor economic status. On the other hand, its being 24 hours has made it available for the people who work and cannot go to outpatient centers during the day.

Some of these visits may be requested by emergency physicians for medical patients, with non-urgent psychiatric signs and symptoms and even 28.6% of needs to revisit were due to the unsuitable level of consciousness or the existence of medical emergencies. This emphasizes the impotence of increasing coordination and cooperation between emergency physicians and psychiatrists to reduce time and expenses. Furthermore, medical professionals and patients may differ in what they assume as a medical emergency is (19). This also may be true for emergency psychiatric situations and having more studies about public attitude to emergency psychiatric problem could be useful.

In this study, 47% of patients needed to be hospitalized which is very close to western countries (20) and differs from 77.9% in Khalili and Yasami's study (21) which is probably because of not having as many samples as that study or maybe it is because of the sooner time of treatment in our samples due to better socioeconomic conditions based on their geographical location, because in that study this differs between two hospitals too and 68.4% of patients in Talegani and 80.1% of patients in Imam Hosein hospital needed hospitalization, although differences between the two hospitals were not statically meaningful. Furthermore, there have been better outpatient psychiatric services and less stigma of visiting psychiatrist in recent years.

In this study, 75% of patients were not hospitalized due to insufficient beds and 18.7% for not having essential facilities like isolation room for aggressive patients which is high

percentage like the study of Khalili and Yesami(21)and necessitates the need to make more psychiatric wards and preventive services.

Like the study carried out by Khalili and Yasmi(21)and smith et al.(6), educational level, marital status, ageand gender were not related to the need to be hospitalized in this study,however, job status, medical disease and pervious psychiatric disorders were related, butunlike this study, it was shown that there is a direct relation between substance abuse and the need to be hospitalized in the mentioned studies. This is probably because of the fact that weincluded both current and previous substanceabusers in our study or it could be for the fact that we had fewer samples in comparison with those mentioned studies.

The limitations of this study must be mentioned. First we did not evaluate some important variables like economic status and support system. Second, our sample was not large enough. Future studies should address these issues in larger sample sizes.

Author's Contributions

AGhJ and MNI conceived and designed the evaluation, and interpreted the clinical data. AGhJ performed parts of the statistical analysis and drafted the manuscript. FSh collected the clinical data and performed parts of the statistical analysis. All authors read and approved the final manuscript.
