Abstract

Background: Most students perceive a dormitory as their home. Research suggests that inappropriate conditions of dormitories can disrupt the psychophysical health and educational status of students.

Objectives: The present research was conducted in 2016 to investigate the status of the environmental hygiene and house dust mites (HDMs) in dormitories for the female students of Kermanshah University of Medical Sciences, Kermanshah, Iran. The status of dust in terms of HDMs was also examined in different areas of the dormitories, including the rooms.

Methods: To investigate the environmental parameters, a checklist comprising 14 sections was developed and completed through a field survey. To investigate the prevalence of mites, the samples collected from 1 m² of the surface of the mattresses and carpets in the rooms using a vacuum cleaner were extracted and stained, and the mites were counted under a microscope.

Results: One sample positive for mites was identified in both Boostan and Taleghani dormitories, while no positive samples were found in Mofatteh dormitory. Moderate levels of environmental hygiene were also observed in Mofatteh dormitory and favorable levels in Boostan and Taleghani.

Conclusions: The results obtained from the present research suggest that the health status of the dormitories was moderate to high based on their overall score; nevertheless, the buildings oldness and the lack of a consistent management of waste collection and sewage disposal were among the factors that degraded the health status of all the dormitories.

Keywords: HDM, Dormitory, Environmental Hygiene, Student, Dust

1. Background

Many students perceive entering a university, including the experience of living in a dormitory, as the beginning of a new stage of their life. Given the large number of students annually admitted to universities outside their place of residence, dormitories are considered a substitute for their family environment (1). In 1996, Johnson et al. showed that living in dormitories and their hygienic status increase students' tolerance, develop their psychosocial characteristics, self-confidence and critical thinking and help with their adaptation to the community, participation in non-teaching activities and mental maturity (2). Research suggests that good health can improve the learning potential, and that a healthy and systematic learning environment is required for ensuring psychophysical health as an essential component of efficient learning (3). In 2004,

Bahreini et al. found inappropriate conditions of dormitories to disrupt the psychophysical health and educational status of students (4). In Iran, the number of student dormitories has increased proportionally to the recently-growing student population. According to the statistics adopted from the ISNA website, in 2015, the total number of Iranian university students was 4400000, including 92457 in Kermanshah, and 45% of the students were living in dormitories (5). Given the importance of the hygiene of dormitories as the place of residence of students, significant health factors and their standards are categorized in Table 1.

2. Objectives

The present study was conducted in 2016 to investigate the environmental hygiene status of dormitories for

Table 1. Significant Health Factors and Their Standards in Student Dormitories

Health Items	Standards
Provide safe drinking water	Access to safe sanitary water
Collection and proper disposal of waste materials	At least 2 days once (6)
Collection and proper use of sewage	Lack of seizure of sewage and lack of accumulation of sewage
Control and fight against insects and rodents	Equipped with windows to the grid, the existence of a regular refinement and spraying program
Create an environment improvement facility	There is a curriculum to rehabilitate and improve the environment
Provide general cleaning	Regular dusting, cleaning and repairing failures
Ambient lighting	Bedroom: 100 to 50 lx
	Study table: 500 lx
	Living room: 200 lx (6)
Air requirement	0.7 - 1 per hour (7)
Ventilation	At least 45% of the window level should be opened / the area and size of the ventilation valve per cubic meter of the room is equal to 100 m ² (6)
Moisture	40% (6)
Temperature	20°C (6)
Dust	-
Mite	-

female students of Kermanshah University of Medical Sciences. The different areas of the dormitories evaluated included the building and rooms, sanitary facilities, study halls and buffets.

3. Methods

3.1. Field Data Collection

The present descriptive cross-sectional study was conducted on a population comprising dormitories for females students of Kermanshah University of Medical Sciences, namely Shahid Mofatteh, Boostan and Taleghani. Table 2 presents the details of these dormitories.

3.2. Collecting Data About Health Parameters in Dormitories

Table 3 presents the study parameters. To investigate these parameters, a checklist comprising 14 sections was developed according to library information and the existing standards and regulations of the Iranian Ministry of Health, and completed through field inspections for each dormitory. Before being included in calculating the overall score, the study parameters were given weighting factors based on the advice of environmental health experts.

3.3. Data Analysis

The score obtained for each parameter was multiplied by its weight, and the average of that parameter was calculated in different rooms. The overall score of the parameter was then determined on a three-point Likert scale, including poor: 0 - 0.33; moderate: 0.33 - 0.66 and favorable:

0.66 - 1. The data obtained were plotted in Microsoft Excel 2010, and humidity, temperature, light (based on the ratio of the window surface to the internal surface of the room) and dust were expressed with measures of dispersion, including mean, minimum and maximum.

3.4. Prevalence of Mites in the Study Rooms

To investigate the prevalence of HDMs, 1 m² of the study surfaces, including mattresses and carpets, was sampled using a vacuum cleaner with a suction flow of 95.8 L/min. The dust collected in the vacuum cleaner cyclone was weighed with a digital scale, sifted using a mesh sieve with 500 micron-pores, and then divided into three parts, each of which was suspended in 25 mL of a saline solution containing 9% caustic soda and 3 drops of detergent in a 50-mL propylene tube, and vortexed for 20 seconds. The suspension was passed through a mesh with 235- μ m pores, and the residue was washed with distilled water in a clean sample container, and then stained with crystal violet, which causes all the components of the dust sample to be stained except for HDMs. It is worth noting that detecting mites is easier against a purple background. A microscope made by Carl Zeiss Jena was used with low magnifications of X25 and X40 to count HDMs. The number of HDMs was determined and their density calculated in each of the three sub-samples as the number of HDMs per gram of dust. To investigate HDMs and temperature and humidity in each room, a sample size of 114 was obtained as the number of study rooms using the Morgan table.

Table 2. Details of the Dormitories for Female Students of Kermanshah University of Medical Sciences

Unit Name	Number of Floors	Number of Rooms	Sub-Basement (m ²)	Number of Students
1	4	54	1366	271
2	3	64	4100	287
3	2	60	2000	243

Table 3. The Number of Questions in Each Study Group

Parameters Reviewed	Weight Based on Importance	Number of Questions
Prayer room	11	1
kitchen	2	20
General cleaning	3	9
Buffet	1	17
Wastewater	3	7
Garbage	3	16
room	3	17
Building	3	15
Ventilation	3	5
Safety	3	10
Area	1	4
Reading room	1	17
Gym	1	18
Toilet	2	15

3.5. Measuring Environmental Parameters

Humidity and temperature were measured with a thermo-hygrometer made by TFA Dustman Company, and the amount of dust and number of HDMS were examined through sampling the surface unit of the carpets and mattresses.

4. Results and Discussion

4.1. Results Obtained from the Checklists

After the field inspection and completion of the checklist, the results were entered into SPSS and assigned weighting factors based on their health importance, and the scores were classified as poor, moderate and favorable based on the Likert scale. Table 4 presents the health status of the study items in Shahid Mofatteh, Boostan and Taleghani dormitories.

The overall score of Taleghani dormitory was 0.67, Mofatteh 0.6, and Boostan 0.77. According to the Likert scale, the health status of Taleghani and Boostan was favorable and that of Mofatteh moderate. In the majority of the investigated rooms, the health status of the study hall

and the rooms and waste disposal was poor. The health status was better in Boostan dormitory, poor items were not observed, and kitchen, waste disposal, building condition and general health were categorized as moderate. In Taleghani dormitory, sewage disposal and the buffet health status were in poor health conditions. Based on the study parameters in the checklist, the general health status of Boostan dormitory with a score of 0.77 was the best compared to that of the other two.

4.2. Environmental Parameters

The mean room temperature in Mofatteh dormitory was found to be $25.94 \pm 1.57^{\circ}\text{C}$, in Boostan to be $26.835 \pm 1.45^{\circ}\text{C}$ and in Taleghani $26 \pm 1.92^{\circ}\text{C}$. According to Figure 1, the mean humidity was measured as 21% - 48% in the three dormitories. Both the study parameters therefore lay in the standard range.

4.3. Dust Levels and Prevalence of HDMS in the Rooms

Figure 2 shows the measured level of dust in the samples collected from the surfaces of the mattresses, pillows and carpets in the study rooms, suggesting the highest amount of dust in Mofatteh dormitory and the lowest in Taleghani. The completed checklist as per Table 4 also suggests a poor health status for Mofatteh dormitory in terms of all the examined items.

**Figure 1.** Relative humidity in the study dormitories

Table 4. The Status of the Study Health Parameters in the Dormitories

	Dormitory, Condition								
	1			2			3		
	Weak	Medium	Optimal	Weak	Medium	Optimal	Weak	Medium	Optimal
Prayer room	-		100			100			100
Toilet	-		100			100			100
Kitchen	-	87.5	12.5		70.5			100	
Garbage	12.5	87.5			80	20		100	
Building	-	100			100			100	
Safety	-	100				100		100	
Ventilation	-		100			100		100	
Gym	-	100				100		100	
Reading room	100								100
Room	100							100	
Wastewater	-	58.8	41.1				5.8	76.4	17.6
Area	-		100						100
Buffet	-		100				100		
General cleaning	-	100			100	100			

4.4. Relationship Between the Levels of Humidity and Dust

Investigating the dust samples collected from the dormitories found only one sample positive for (dead) mites in both Boostan and Taleghani dormitories, and no positive samples in Mofatteh dormitory. Research suggests humidity is an effective factor in the survival of HDMs. In 1999, Arlien et al. observed the highest number of HDMs at a relative humidity of over 60% (8), which is consistent with the present research failure to identify samples positive for HDMs given the low relative humidity of the sampling sites and the city of Kermanshah as a whole.

4.5. Conclusions

The results obtained from the present research suggest that the health status of the dormitories was moderate to high based on their overall score; nevertheless, the buildings oldness and a lack of a consistent management of waste collection and sewage disposal were among

the most effective factors in the degradation of the health status of all the dormitories. These problems are recommended to be solved by developing short-term, mid-term and long-term plans. In terms of the health status of rooms, training programs are recommended to be implemented to teach students about their individual health and promote their health culture.

Acknowledgments

The authors acknowledge all whom participated in this research, the Kermanshah University of Medical Sciences laboratories, who with their sincere cooperation, facilitated this study.
